Package 'jfa'

March 18, 2021

Title Bayesian and Classical Audit Sampling

Version 0.5.2

Date 2021-03-15

Description Implements the audit sampling workflow as discussed in Derks et al. (2019) <doi:10.31234/osf.io/9f6ub>. The package makes it easy for an auditor to plan an audit sample, sample from the population, and evaluating that sample using various confidence bounds according to the International Standards on Auditing. Furthermore, the package implements Bayesian equivalents of these methods.

R topics documented:

`auditPrior` *Create a Prior Distribution with Existing Audit Information*

Description

This function creates a prior distribution for Bayesian audit sampling according to several methods discussed in Derks et al. (2020). The returned object is of class `jfaPrior` and can be used with associated `print()` and `plot()` methods. `jfaPrior` objects can be used as input for the `prior` argument in other functions.

For more details on how to use this function see the package vignette: `vignette("jfa",package = "jfa")`

Usage

```
auditPrior(confidence = 0.95, likelihood = "binomial", method = "none",
           expectedError = 0, N = NULL, materiality = NULL, ir = 1, cr = 1,
           pHmin = NULL, pHplus = NULL, factor = 1, sampleN = 0, sampleK = 0)
```

Arguments

`confidence`	the confidence level desired from the confidence bound (on a scale from 0 to 1). Defaults to 0.95, or 95% confidence.
`likelihood`	can be one of `binomial`, `poisson`, or `hypergeometric`. See the Details section for more information.
`method`	the method by which the prior distribution is constructed. Defaults to the `none` method, which incorporates no prior information. Can be one of `none`, `median`, `hypotheses`, `arm`, `sample` or `factor`. See the Details section for more information.
`expectedError`	a fraction representing the percentage of expected mistakes in the sample relative to the total size, or a number (>= 1) that represents the number of expected mistakes. It is advised to set this value conservatively to minimize the probability of the observed errors exceeding the expected errors, which would imply that insufficient work has been done.
`N`	the population size (only required when `likelihood = 'hypergeometric'`).
`materiality`	a value between 0 and 1 representing the materiality of the audit as a fraction of the total size or value. Can be `NULL` for some methods.
`ir`	the inherent risk probability from the audit risk model. Defaults to 1 for 100% risk.
`cr`	the inherent risk probability from the audit risk model. Defaults to 1 for 100% risk.
`pHmin`	when using `method = 'hypotheses'`, the prior probability of the hypothesis $\theta <$ materiality.
`pHplus`	when using `method = 'hypotheses'`, the prior probability of the hypothesis $\theta >$ materiality.
`factor`	when using `method = 'factor'`, the value of the weighting factor for the results of the previous sample.
`sampleN`	when using method `sample` or `factor`, the number of transactions that were inspected in the previous sample.
`sampleK`	when using method `sample` or `factor`, the total taint in the previous sample.

Details

This section elaborates on the available likelihoods and corresponding prior distributions for the `likelihood` argument.

- `poisson`: The Poisson likelihood is used as a likelihood for monetary unit sampling (MUS). Its likelihood function is defined as:

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!}$$

  The conjugate *gamma(α, β)* prior has probability density function:

$$f(x; \alpha, \beta) = \frac{\beta^\alpha x^{\alpha-1} e^{-\beta x}}{\Gamma(\alpha)}$$

- `binomial`: The binomial likelihood is used as a likelihood for record sampling *with* replacement. Its likelihood function is defined as:

$$p(x) = \binom{n}{k} p^k (1-p)^{n-k}$$

  The conjugate *beta(α, β)* prior has probability density function:

$$f(x; \alpha, \beta) = \frac{1}{B(\alpha, \beta)} x^{\alpha-1} (1-x)^{\beta-1}$$

- `hypergeometric`: The hypergeometric likelihood is used as a likelihood for record sampling *without* replacement. Its likelihood function is defined as:

$$p(x = k) = \frac{\binom{K}{k}\binom{N-K}{n-k}}{\binom{N}{n}}$$

  The conjugate *beta-binomial(α, β)* prior (Dyer and Pierce, 1993) has probability density function:

$$f(k|n, \alpha, \beta) = \binom{n}{k} \frac{B(k+\alpha, n-k+\beta)}{B(\alpha, \beta)}$$

This section elaborates on the available methods for constructing a prior distribution.

- `none`: This method constructs a prior distribution according to the principle of minimum information.
- `median`: This method constructs a prior distribution so that the prior probabilities of tolerable and intolerable misstatement are equal.
- `hypotheses`: This method constructs a prior distribution with specified prior probabilities for the hypotheses of tolerable and intolerable misstatement. Requires specification of the `pHmin` and `pHplus` arguments.
- `arm`: This method constructs a prior distribution according to the assessed risks in the audit risk model. Requires specification of the `ir` and `cr` arguments.
- `sample`: This method constructs a prior distribution on the basis of an earlier sample. Requires specification of the `sampleN` and `sampleK` arguments.
- `factor`: This method constructs a prior distribution on the basis of last year's results and a weighting factor. Requires specification of the `factor`, `sampleN` and `sampleK` arguments.

Value

An object of class `jfaPrior` containing:

`confidence`	the method by which the prior distribution is constructed.
`likelihood`	the likelihood by which the prior distribution is updated.
`method`	the method by which the prior distribution is constructed.
`expectedError`	the expected error input.
`N`	if specified as input, the population size.
`materiality`	if specified, the materiality that was used to construct the prior distribution.
`description`	a description of the prior distribution, including parameters and the implicit sample.
`statistics`	a list of statistics of the prior distribution, including the mean, mode, median, and upper bound.
`specifics`	a list of optional specifications of the prior distribution, these depend on the method used.
`hypotheses`	if a materiality is specified, a list of statistics about the hypotheses including prior probabilities and odds.

`BuildIt` *BuildIt Construction financial statements*

Description

Fictional data from a construction company in the United States, containing 3500 observations identification numbers, book values, and audit values. The audit values are added for illustrative purposes, as these would need to be assessed by the auditor in the execution stage of the audit.

Usage

```
data(BuildIt)
```

Format

A data frame with 3500 rows and 3 variables.

ID unique record identification number.

bookValue book value in US dollars ($14.47–$2,224.40).

auditValue true value in US dollars ($14.47–$2,224.40).

`evaluation` *Evaluation of Audit Samples using Confidence / Credible Bounds*

Description

This function takes a data frame (using `sample`, `bookValues`, and `auditValues`) or summary statistics (using `nSumstats` and `kSumstats`) and evaluates the audit sample according to the specified method. The returned object is of class `jfaEvaluation` and can be used with associated `print()` and `plot()` methods.

For more details on how to use this function see the package vignette: `vignette("jfa",package = "jfa")`

Usage

```
evaluation(confidence = 0.95, method = "binomial", N = NULL,
           sample = NULL, bookValues = NULL, auditValues = NULL, counts = NULL,
           nSumstats = NULL, kSumstats = NULL,
           materiality = NULL, minPrecision = NULL,
           prior = FALSE, nPrior = 0, kPrior = 0,
       rohrbachDelta = 2.7, momentPoptype = "accounts", populationBookValue = NULL,
           csA = 1, csB = 3, csMu = 0.5)
```

Arguments

`confidence`	the required confidence level for the bound. Default is 0.95 for 95% confidence.
`method`	the method that is used to evaluate the sample. This can be either one of `poisson`, `binomial`, `hypergeometric`, `mpus`, `stringer`, `stringer-meikle`, `stringer-lta`, `stringer-pvz`, `rohrbach`, `moment`, `direct`, `difference`, `quotient`, or `regression`.
`N`	an integer specifying the total number of units (transactions or monetary units) in the population.
`sample`	a data frame containing at least a column of Ist values and a column of Soll (true) values.
`bookValues`	a character specifying the column name for the Ist values in the sample.
`auditValues`	a character specifying the column name for the Soll values in the sample.
`counts`	a integer vector of the number of times each transaction in the sample is to be evaluated (due to it being selected multiple times for the sample).
`nSumstats`	an integer specifying the number of transactions in the sample. If specified, overrides the `sample`, `bookValues` and `auditValues` arguments and assumes that the data come from summary statistics specified by both `nSumstats` and `kSumstats`.
`kSumstats`	a value specifying the sum of taints (proportional errors) found in the sample. If specified, overrides the `sample`, `bookValues` and `auditValues` arguments and assumes that the data come from summary statistics specified by both `kSumstats` and `nSumstats`.

`materiality` a value specifying the performance materiality as a fraction of the total value (or size) of the population (a value between 0 and 1). If specified, the function also returns the conclusion of the analysis with respect to the performance materiality. The value is discarded when `direct`, `difference`, `quotient`, or `regression` method is chosen.

`minPrecision` a value specifying the required minimum precision. If specified, the function also returns the conclusion of the analysis with respect to the required minimum precision. This value must be specified as a fraction of the total value of the population (a value between 0 and 1).

`prior` a logical indicating whether to use a prior distribution when evaluating. Defaults to `FALSE` for frequentist evaluation. If `TRUE`, the prior distribution is updated by the corresponding likelihood. Chooses a conjugate gamma distribution for the Poisson likelihood, a conjugate beta distribution for the binomial likelihood, and a conjugate beta-binomial distribution for the hypergeometric likelihood.

`nPrior` a value for the prior parameter β (number of transactions in the assumed prior sample).

`kPrior` a value for the prior parameter α (total tainting in the assumed prior sample).

`rohrbachDelta` a value specifying Δ in Rohrbach's augmented variance bound (Rohrbach, 1993).

`momentPoptype` a character specifying the type of population for the modified moment method (Dworin and Grimlund, 1984). Can be either one of `accounts` or `inventory`. Options result in different methods for calculating the central moments.

`populationBookValue` a value specifying the total value of the transactions in the population. Required when `method` is one of `direct`, `difference`, `quotient`, or `regression`, but optional otherwise.

`csA` if `method = "coxsnell"`, the α parameter of the prior distribution on the mean taint. Default is set to 1, as recommended by Cox and Snell (1979).

`csB` if `method = "coxsnell"`, the β parameter of the prior distribution on the mean taint. Default is set to 3, as recommended by Cox and Snell (1979).

`csMu` if `method = "coxsnell"`, the mean of the prior distribution on the mean taint. Default is set to 0.5, as recommended by Cox and Snell (1979).

Details

This section lists the available options for the `methods` argument.

- `poisson`: The confidence bound taken from the Poisson distribution. If combined with `prior = TRUE`, performs Bayesian evaluation using a *gamma* prior and posterior.
- `binomial`: The confidence bound taken from the binomial distribution. If combined with `prior = TRUE`, performs Bayesian evaluation using a *beta* prior and posterior.
- `hypergeometric`: The confidence bound taken from the hypergeometric distribution. If combined with `prior = TRUE`, performs Bayesian evaluation using a *beta-binomial* prior and posterior.
- `mpu`: Mean per unit estimator using the observed sample taints.
- `stringer`: The Stringer bound (Stringer, 1963).
- `stringer-meikle`: Stringer bound with Meikle's correction for understatements (Meikle, 1972).
- `stringer-lta`: Stringer bound with LTA correction for understatements (Leslie, Teitlebaum, and Anderson, 1979).

- `stringer-pvz`: Stringer bound with Pap and van Zuijlen's correction for understatements (Pap and van Zuijlen, 1996).
- `rohrbach`: Rohrbach's augmented variance bound (Rohrbach, 1993).
- `moment`: Modified moment bound (Dworin and Grimlund, 1984).
- `coxsnell`: Cox and Snell bound (Cox and Snell, 1979).
- `direct`: Confidence interval using the direct method (Touw and Hoogduin, 2011).
- `difference`: Confidence interval using the difference method (Touw and Hoogduin, 2011).
- `quotient`: Confidence interval using the quotient method (Touw and Hoogduin, 2011).
- `regression`: Confidence interval using the regression method (Touw and Hoogduin, 2011).

Value

An object of class `jfaEvaluation` containing:

`confidence`	a value specifying the confidence level of the result.
`method`	the evaluation method that was used.
`N`	if `N` is specified, the population size that is used.
`n`	an integer specifying the sample size used in the evaluation.
`k`	an integer specifying the number of transactions that contained an error.
`t`	a value specifying the sum of observed taints.
`materiality`	if `materiality` is specified, the performance materiality used.
`minPrecision`	if `minPrecision` is specified, the minimum required precision used.
`mle`	a value specifying the most likely error in the population as a proportion.
`precision`	a value specifying the difference between the mle and the upper confidence bound as a proportion.
`popBookvalue`	if specified as input, the total Ist value of the population.
`pointEstimate`	if method is one of `direct`, `difference`, `quotient`, or `regression`, the value of the point estimate.
`lowerBound`	if method is one of `direct`, `difference`, `quotient`, or `regression`, the value of the lower bound of the interval.
`upperBound`	if method is one of `direct`, `difference`, `quotient`, or `regression`, the value of the upper bound of the interval.
`confBound`	the upper confidence bound on the error percentage.
`conclusion`	if `materiality` is specified, the conclusion about whether to approve or not approve the population.
`populationK`	the assumed total errors in the population. Used in inferences with `hypergeometric` method.
`prior`	an object of class 'jfaPrior' to represents the prior distribution.
`posterior`	an object of class 'jfaPosterior' to represents the posterior distribution.
`data`	a data frame containing the relevant columns from the `sample` input.

`planning` *Frequentist and Bayesian Planning for Audit Sampling*

Description

This function calculates the required sample size for an audit, based on the Poisson, binomial, or hypergeometric likelihood. A prior can be specified to perform Bayesian planning. The returned object is of class `jfaPlanning` and can be used with associated `print()` and `plot()` methods.

For more details on how to use this function see the package vignette: `vignette("jfa",package = "jfa")`

Usage

```
planning(confidence = 0.95, expectedError = 0, likelihood = "poisson", N = NULL,
         materiality = NULL, minPrecision = NULL,
         prior = FALSE, kPrior = 0, nPrior = 0,
         increase = 1, maxSize = 5000)
```

Arguments

`confidence`	the confidence level desired from the confidence bound (on a scale from 0 to 1). Defaults to 0.95, or 95% confidence.
`expectedError`	a fraction representing the percentage of expected mistakes in the sample relative to the total size, or a number (>= 1) that represents the number of expected mistakes. It is advised to set this value conservatively to minimize the probability of the observed errors exceeding the expected errors, which would imply that insufficient work has been done.
`likelihood`	can be one of `binomial`, `poisson`, or `hypergeometric`.
`N`	the population size (required for hypergeometric calculations).
`materiality`	a value between 0 and 1 representing the materiality of the audit as a fraction of the total size or value. Can be `NULL`, but `minPrecision` should be specified in that case.
`minPrecision`	The minimum precision to be obtained. Can be `NULL`, but `materiality` should be specified in that case.
`prior`	whether to use a prior distribution when planning. Defaults to `FALSE` for frequentist planning. If `TRUE`, the prior distribution is updated by the specified likelihood. Chooses a conjugate gamma distribution for the Poisson likelihood, a conjugate beta distribution for the binomial likelihood, and a conjugate beta-binomial distribution for the hypergeometric likelihood.
`kPrior`	the prior parameter α (number of errors in the assumed prior sample).
`nPrior`	the prior parameter β (total number of observations in the assumed prior sample).
`increase`	the desired increase step for the sample size calculation.
`maxSize`	the maximum sample size that is considered for calculations. Defaults to 5000 for efficiency. Increase this value if the sample size cannot be found due to it being too large (e.g., for a low materiality).

Details

This section elaborates on the available likelihoods and corresponding prior distributions for the `likelihood` argument.

- `poisson`: The Poisson likelihood is used as a likelihood for monetary unit sampling (MUS). Its likelihood function is defined as:

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!}$$

The conjugate *gamma*(α, β) prior has probability density function:

$$f(x; \alpha, \beta) = \frac{\beta^\alpha x^{\alpha-1} e^{-\beta x}}{\Gamma(\alpha)}$$

- `binomial`: The binomial likelihood is used as a likelihood for record sampling *with* replacement. Its likelihood function is defined as:

$$p(x) = \binom{n}{k} p^k (1-p)^{n-k}$$

The conjugate *beta*(α, β) prior has probability density function:

$$f(x; \alpha, \beta) = \frac{1}{B(\alpha, \beta)} x^{\alpha-1} (1-x)^{\beta-1}$$

- `hypergeometric`: The hypergeometric likelihood is used as a likelihood for record sampling *without* replacement. Its likelihood function is defined as:

$$p(x = k) = \frac{\binom{K}{k}\binom{N-K}{n-k}}{\binom{N}{n}}$$

The conjugate *beta-binomial*(α, β) prior (Dyer and Pierce, 1993) has probability density function:

$$f(k|n, \alpha, \beta) = \binom{n}{k} \frac{B(k+\alpha, n-k+\beta)}{B(\alpha, \beta)}$$

Value

An object of class `jfaPlanning` containing:

`confidence`	the confidence level for the desired population statement.
`expectedError`	the specified number of errors as a fraction or as a number.
`likelihood`	the specified likelihood.
`N`	the population size (only returned in case of a hypergeometric likelihood).
`materiality`	the value of the specified materiality. Can be `NULL`.
`minPrecision`	The minimum precision to be obtained. Can be `NULL`.
`sampleSize`	the resulting sample size.
`errorType`	whether the expected errors where specified as a percentage or as an integer.
`expectedSampleError`	the number of full errors that are allowed to occur in the sample.
`expectedBound`	a value specifying the expected upper bound if the sample goes according to plan.
`expectedPrecision`	a value specifying the expected precision if the sample goes according to plan.
`populationK`	the assumed population errors (only returned in case of a hypergeometric likelihood).
`prior`	an object of class `jfaPrior` that represents the prior distribution.
`expectedPosterior`	an object of class `jfaPosterior` that represents the expected posterior distribution.

`report` *Generate an Audit Report*

Description

This function takes an object of class `jfaEvaluation`, creates a report containing the results, and saves the report to a file in your working directory.

For more details on how to use this function see the package vignette: `vignette("jfa",package = "jfa")`

Usage

```
report(object = NULL, file = NULL, format = "html_document")
```

Arguments

`object`	an object of class `jfaEvaluation` as returned by the `evaluation()` function.
`file`	a string that gives the desired name of the file (e.g. `"report.html"`). The report is created in your current working directory.
`format`	can be either one of `"html_document"` or `"pdf_document"` (compiling to pdf requires MikTex).

Value

A html or pdf report containing the results of the evaluation.

Examples

```
library(jfa)
set.seed(1)

# Generate some audit data (N = 1000):
data <- data.frame(ID = sample(1000:100000, size = 1000, replace = FALSE),
                   bookValue = runif(n = 1000, min = 700, max = 1000))

# Using monetary unit sampling, draw a random sample from the population.
s1 <- selection(population = data, sampleSize = 100, units = "mus",
                bookValues = "bookValue", algorithm = "random")
s1_sample <- s1$sample
s1_sample$trueValue <- s1_sample$bookValue
s1_sample$trueValue[2] <- s1_sample$trueValue[2] - 500 # One overstatement is found

e2 <- evaluation(sample = s1_sample, bookValues = "bookValue", auditValues = "trueValue",
                 method = "stringer", materiality = 0.05, counts = s1_sample$counts)

# Generate report
# report(e2, file = "myFile.html")
```

`selection` *Selecting a Sample from an Audit Population*

Description

This function takes a data frame and performs sampling according to one of three popular algorithms: random sampling, cell sampling, or fixed interval sampling. Sampling is done in combination with one of two sampling units: records or monetary units The returned object is of class `jfaSelection` and can be used with associated `print()` and `plot()` methods.

For more details on how to use this function see the package vignette: `vignette("jfa",package = "jfa")`

Usage

```
selection(population, sampleSize, units = "records", algorithm = "random",
          bookValues = NULL, intervalStartingPoint = 1, ordered = TRUE,
          ascending = TRUE, withReplacement = FALSE, seed = 1)
```

Arguments

`population`	a data frame containing the population the auditor wishes to sample from.
`sampleSize`	the number of observations that need to be selected from the population. Can also be an object of class `jfaPlanning`.
`units`	can be either `records` (default) for record sampling, or `mus` for monetary unit sampling.
`algorithm`	can be either one of `random` (default) for random sampling, `cell` for cell sampling, or `interval` for fixed interval sampling.
`bookValues`	a character specifying the name of the column containing the book values (as in the population data).

intervalStartingPoint	the starting point in the interval (used only in fixed interval sampling)
ordered	if TRUE (default), the population is first ordered according to the value of their book values.
ascending	if TRUE (default), order the population in ascending order.
withReplacement	whether sampling should be performed with replacement. Defaults to FALSE.
seed	seed to reproduce results. Default is 1.

Details

This first part of this section elaborates on the possible options for the units argument:

- records: In record sampling, each observation in the population is seen as a sampling unit. An observation of $5000 is therefore equally likely to be selected as an observation of $500.
- mus: In monetary unit sampling, each monetary unit in the population is seen as a sampling unit. An observation of $5000 is therefore ten times more likely to be selected as an observation of $500.

This second part of this section elaborates on the possible options for the algorithm argument:

- random: In random sampling each sampling unit in the population is drawn with equal probability.
- cell: In cell sampling the sampling units in the population are divided into a number (equal to the sample size) of intervals. From each interval one sampling unit is selected with equal probability.
- interval: In fixed interval sampling the sampling units in the population are divided into a number (equal to the sample size) of intervals. From each interval one sampling unit is selected according to a fixed starting point (intervalStartingPoint).

Value

An object of class jfaSelection containing:

population	a data frame containing the input population.
sample	a data frame containing the selected observations.
units	the sampling units that were used for sampling.
algorithm	the algorithm that was used for sampling.
bookValues	if specified, the name of the specified book value column.
