Package 'jfa'

March 23, 2021

Title Bayesian and Classical Audit Sampling

Version 0.5.2

Date 2021-03-15

Description Implements the audit sampling workflow as discussed in Derks et al. (2019) <doi:10.31234/osf.io/9f6ub>. The package makes it easy for an auditor to plan an audit sample, sample from the population, and evaluating that sample using various confidence bounds according to the International Standards on Auditing. Furthermore, the package implements Bayesian equivalents of these methods.

auditPrior *Create a Prior Distribution with Existing Audit Information*

Description

This function creates a prior distribution with audit information to be used in the `planning()` and `evaluation()` functions via their `prior` argument. The returned object is of class `jfaPrior` and has a `print()` and `plot()` method.

For more details on how to use this function see the package vignette: `vignette('jfa',package = 'jfa')`

Usage

```
auditPrior(confidence = 0.95, likelihood = 'binomial', method = 'none',
          expectedError = 0, N = NULL, materiality = NULL, ir = 1, cr = 1,
          pHmin = NULL, pHplus = NULL, factor = 1, sampleN = 0, sampleK = 0)
```

Arguments

confidence	a value between 0 and 1 specifying the confidence level desired for the sample planning. Defaults to 0.95 for 95% confidence.
likelihood	a character specifying the likelihood assumed when updating the prior distribution. This can be either `binomial` for the binomial likelihood and beta prior distribution, `poisson` for the Poisson likelihood and gamma prior distribution, or `hypergeometric` for the hypergeometric likelihood and beta-binomial prior distribution. See the details section for more information about the available likelihoods.
method	a character specifying the method by which the prior distribution is constructed. Defaults to the `none` method, which incorporates no existing information. Other options are `median`, `hypotheses`, `arm`, `sample` or `factor`. See the details section for more information about these methods.
expectedError	a value between 0 and 1 specifying the expected errors in the sample relative to the total sample size, or a number (>= 1) that represents the number of expected errors in the sample. It is advised to set this value conservatively to minimize the probability of the observed errors exceeding the expected errors, which would imply that insufficient work has been done in the end.
N	an integer (or value) specifying the total population size (or value). Only required when `likelihood = 'hypergeometric'`.
materiality	a value between 0 and 1 specifying the performance materiality (i.e., maximum upper limit) of the audit as a fraction of the total size (or value). Can be NULL for some methods.
ir	if `method = 'arm'`, a value between 0 and 1 specifying the inherent risk probability from the audit risk model. Defaults to 1 for 100% risk.
cr	if `method = 'arm'`, a value between 0 and 1 specifying the internal control risk probability from the audit risk model. Defaults to 1 for 100% risk.
pHmin	if `method = 'hypotheses'`, a value between 0 and 1 specifying the prior probability of the hypothesis $\theta <$ materiality.

pHplus	if method = 'hypotheses', a value between 0 and 1 specifying the prior probability of the hypothesis $\theta >$ materiality.
factor	if method = 'factor', a value between 0 and 1 specifying the weighting factor for the results of the earlier sample.
sampleN	if method = 'sample' or method = 'factor', an integer specifying the number of sampling units that were inspected in the earlier sample.
sampleK	if sample or factor, a value specifying the sum of errors in the previous sample.

Details

This section elaborates on the available likelihoods and corresponding prior distributions for the likelihood argument.

- poisson: The Poisson likelihood is used as a likelihood for monetary unit sampling (MUS). Its likelihood function is defined as:

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!}$$

The conjugate *gamma(α, β)* prior has probability density function:

$$f(x; \alpha, \beta) = \frac{\beta^\alpha x^{\alpha-1} e^{-\beta x}}{\Gamma(\alpha)}$$

- binomial: The binomial likelihood is used as a likelihood for record sampling *with* replacement. Its likelihood function is defined as:

$$p(x) = \binom{n}{k} p^k (1-p)^{n-k}$$

The conjugate *beta(α, β)* prior has probability density function:

$$f(x; \alpha, \beta) = \frac{1}{B(\alpha, \beta)} x^{\alpha-1} (1-x)^{\beta-1}$$

- hypergeometric: The hypergeometric likelihood is used as a likelihood for record sampling *without* replacement. Its likelihood function is defined as:

$$p(x = k) = \frac{\binom{K}{k}\binom{N-K}{n-k}}{\binom{N}{n}}$$

The conjugate *beta-binomial(α, β)* prior (Dyer and Pierce, 1993) has probability density function:

$$f(k|n, \alpha, \beta) = \binom{n}{k} \frac{B(k+\alpha, n-k+\beta)}{B(\alpha, \beta)}$$

This section elaborates on the available methods for constructing a prior distribution.

- none: This method constructs a prior distribution according to the principle of minimum information.
- median: This method constructs a prior distribution so that the prior probabilities of tolerable and intolerable misstatement are equal.
- hypotheses: This method constructs a prior distribution with specified prior probabilities for the hypotheses of tolerable and intolerable misstatement. Requires specification of the pHmin and pHplus arguments.

- arm: This method constructs a prior distribution according to the assessed risks in the audit risk model. Requires specification of the ir and cr arguments.
- sample: This method constructs a prior distribution on the basis of an earlier sample. Requires specification of the sampleN and sampleK arguments.
- factor: This method constructs a prior distribution on the basis of last year's results and a weighting factor. Requires specification of the factor, sampleN and sampleK arguments.

Value

An object of class jfaPrior containing:

confidence	a fraction indicating the confidence level for the desired population statement.
likelihood	a character indicating the specified likelihood.
method	a character indicating the method by which the prior distribution is constructed.
expectedError	a value indicating the input for the number of expected errors.
N	if N is specified, an integer indicating the population size.
materiality	if materiality is specified, a value between 0 and 1 indicating the materiality that was used to construct the prior distribution.
description	a list containing a description of the prior distribution, including parameters and the implicit sample.
statistics	a list containing statistics of the prior distribution, including the mean, mode, median, and upper bound.
specifics	a list containing optional specifications of the prior distribution that vary depending on the method used.
hypotheses	if materiality is specified, a list containing information about the hypotheses, including prior probabilities and odds.

BuildIt   *BuildIt Construction financial statements*

Description

Fictional data from a construction company in the United States, containing 3500 observations identification numbers, book values, and audit values. The audit values are added for illustrative purposes, as these would need to be assessed by the auditor in the execution stage of the audit.

Usage

```
data(BuildIt)
```

Format

A data frame with 3500 rows and 3 variables.

ID unique record identification number.

bookValue book value in US dollars ($14.47–$2,224.40).

auditValue true value in US dollars ($14.47–$2,224.40).

---

evaluation	*Evaluation of Audit Samples using Confidence / Credible Bounds*

Description

This function takes a data frame (using `sample`, `bookValues`, and `auditValues`) or summary statistics (using `nSumstats` and `kSumstats`) and evaluates the audit sample according to the specified method. The returned object is of class `jfaEvaluation` and can be used with associated `print()` and `plot()` methods.

For more details on how to use this function see the package vignette: `vignette("jfa",package = "jfa")`

Usage

```
evaluation(confidence = 0.95, method = "binomial", N = NULL,
           sample = NULL, bookValues = NULL, auditValues = NULL, counts = NULL,
           nSumstats = NULL, kSumstats = NULL,
           materiality = NULL, minPrecision = NULL,
           prior = FALSE, nPrior = 0, kPrior = 0,
        rohrbachDelta = 2.7, momentPoptype = "accounts", populationBookValue = NULL,
           csA = 1, csB = 3, csMu = 0.5)
```

Arguments

confidence	the required confidence level for the bound. Default is 0.95 for 95% confidence.
method	the method that is used to evaluate the sample. This can be either one of `poisson`, `binomial`, `hypergeometric`, `mpus`, `stringer`, `stringer-meikle`, `stringer-lta`, `stringer-pvz`, `rohrbach`, `moment`, `direct`, `difference`, `quotient`, or `regression`.
N	an integer specifying the total number of units (transactions or monetary units) in the population.
sample	a data frame containing at least a column of Ist values and a column of Soll (true) values.
bookValues	a character specifying the column name for the Ist values in the sample.
auditValues	a character specifying the column name for the Soll values in the sample.
counts	a integer vector of the number of times each transaction in the sample is to be evaluated (due to it being selected multiple times for the sample).

nSumstats	an integer specifying the number of transactions in the sample. If specified, overrides the sample, bookValues and auditValues arguments and assumes that the data come from summary statistics specified by both nSumstats and kSumstats.
kSumstats	a value specifying the sum of taints (proportional errors) found in the sample. If specified, overrides the sample, bookValues and auditValues arguments and assumes that the data come from summary statistics specified by both kSumstats and nSumstats.
materiality	a value specifying the performance materiality as a fraction of the total value (or size) of the population (a value between 0 and 1). If specified, the function also returns the conclusion of the analysis with respect to the performance materiality. The value is discarded when direct, difference, quotient, or regression method is chosen.
minPrecision	a value specifying the required minimum precision. If specified, the function also returns the conclusion of the analysis with respect to the required minimum precision. This value must be specified as a fraction of the total value of the population (a value between 0 and 1).
prior	a logical indicating whether to use a prior distribution when evaluating. Defaults to FALSE for frequentist evaluation. If TRUE, the prior distribution is updated by the corresponding likelihood. Chooses a conjugate gamma distribution for the Poisson likelihood, a conjugate beta distribution for the binomial likelihood, and a conjugate beta-binomial distribution for the hypergeometric likelihood.
nPrior	a value for the prior parameter β (number of transactions in the assumed prior sample).
kPrior	a value for the prior parameter α (total tainting in the assumed prior sample).
rohrbachDelta	a value specifying Δ in Rohrbach's augmented variance bound (Rohrbach, 1993).
momentPoptype	a character specifying the type of population for the modified moment method (Dworin and Grimlund, 1984). Can be either one of accounts or inventory. Options result in different methods for calculating the central moments.
populationBookValue	
	a value specifying the total value of the transactions in the population. Required when method is one of direct, difference, quotient, or regression, but optional otherwise.
csA	if method = "coxsnell", the α parameter of the prior distribution on the mean taint. Default is set to 1, as recommended by Cox and Snell (1979).
csB	if method = "coxsnell", the β parameter of the prior distribution on the mean taint. Default is set to 3, as recommended by Cox and Snell (1979).
csMu	if method = "coxsnell", the mean of the prior distribution on the mean taint. Default is set to 0.5, as recommended by Cox and Snell (1979).

Details

This section lists the available options for the methods argument.

- poisson: The confidence bound taken from the Poisson distribution. If combined with prior = TRUE, performs Bayesian evaluation using a *gamma* prior and posterior.

- binomial: The confidence bound taken from the binomial distribution. If combined with prior = TRUE, performs Bayesian evaluation using a *beta* prior and posterior.

- hypergeometric: The confidence bound taken from the hypergeometric distribution. If combined with prior = TRUE, performs Bayesian evaluation using a *beta-binomial* prior and posterior.
- mpu: Mean per unit estimator using the observed sample taints.
- stringer: The Stringer bound (Stringer, 1963).
- stringer-meikle: Stringer bound with Meikle's correction for understatements (Meikle, 1972).
- stringer-lta: Stringer bound with LTA correction for understatements (Leslie, Teitlebaum, and Anderson, 1979).
- stringer-pvz: Stringer bound with Pap and van Zuijlen's correction for understatements (Pap and van Zuijlen, 1996).
- rohrbach: Rohrbach's augmented variance bound (Rohrbach, 1993).
- moment: Modified moment bound (Dworin and Grimlund, 1984).
- coxsnell: Cox and Snell bound (Cox and Snell, 1979).
- direct: Confidence interval using the direct method (Touw and Hoogduin, 2011).
- difference: Confidence interval using the difference method (Touw and Hoogduin, 2011).
- quotient: Confidence interval using the quotient method (Touw and Hoogduin, 2011).
- regression: Confidence interval using the regression method (Touw and Hoogduin, 2011).

Value

An object of class jfaEvaluation containing:

confidence	a value specifying the confidence level of the result.
method	the evaluation method that was used.
N	if N is specified, the population size that is used.
n	an integer specifying the sample size used in the evaluation.
k	an integer specifying the number of transactions that contained an error.
t	a value specifying the sum of observed taints.
materiality	if materiality is specified, the performance materiality used.
minPrecision	if minPrecision is specified, the minimum required precision used.
mle	a value specifying the most likely error in the population as a proportion.
precision	a value specifying the difference between the mle and the upper confidence bound as a proportion.
popBookvalue	if specified as input, the total Ist value of the population.
pointEstimate	if method is one of direct, difference, quotient, or regression, the value of the point estimate.
lowerBound	if method is one of direct, difference, quotient, or regression, the value of the lower bound of the interval.
upperBound	if method is one of direct, difference, quotient, or regression, the value of the upper bound of the interval.
confBound	the upper confidence bound on the error percentage.
conclusion	if materiality is specified, the conclusion about whether to approve or not approve the population.

populationK	the assumed total errors in the population. Used in inferences with `hypergeometric` method.
prior	an object of class 'jfaPrior' to represents the prior distribution.
posterior	an object of class 'jfaPosterior' to represents the posterior distribution.
data	a data frame containing the relevant columns from the `sample` input.

```

Description

This function calculates the required sample size for an audit, based on the Poisson, binomial or hypergeometric likelihood. A prior distribution can be specified to perform Bayesian planning. The returned object is of class jfaPlanning and has a print() and plot() method.

For more details on how to use this function see the package vignette: vignette('jfa',package = 'jfa')

Usage

```
planning(confidence = 0.95, expectedError = 0, likelihood = 'poisson', N = NULL,
         materiality = NULL, minPrecision = NULL,
         prior = FALSE, kPrior = 0, nPrior = 0,
         increase = 1, maxSize = 5000)
```

Arguments

confidence	a value between 0 and 1 specifying the confidence level desired for the sample planning. Defaults to 0.95 for 95% confidence.
expectedError	a value between 0 and 1 specifying the expected errors in the sample relative to the total sample size, or a number (>= 1) that represents the number of expected errors in the sample. It is advised to set this value conservatively to minimize the probability of the observed errors exceeding the expected errors, which would imply that insufficient work has been done in the end.
likelihood	a character specifying the likelihood assumed in the calculation. This can be either binomial for the binomial likelihood, poisson for the Poisson likelihood, or hypergeometric for the hypergeometric likelihood. See the details section for more information about the available likelihoods.
N	an integer (or value) specifying the total population size (or value). Only required when likelihood = 'hypergeometric'.
materiality	a value between 0 and 1 specifying the performance materiality (i.e., maximum upper limit) of the audit as a fraction of the total size (or value). Can be NULL, but minPrecision should be specified in that case.
minPrecision	a value between 0 and 1 specifying the minimum precision (i.e., upper bound minus most likely error) to be obtained. Can be NULL, but materiality should be specified in that case.
prior	a logical specifying whether to use a prior distribution when planning, or an object of class 'jfaPrior' containing the prior distribution. Defaults to FALSE for frequentist planning. If TRUE, a negligible prior distribution is chosen by default, but can be adjusted using the 'kPrior' and 'nPrior' arguments. Chooses a conjugate gamma distribution for the Poisson likelihood, a conjugate beta distribution for the binomial likelihood, and a conjugate beta-binomial distribution for the hypergeometric likelihood.
kPrior	if prior = TRUE, a value specifying the assumed sum of errors in the implicit sample on which the prior distribution is based.
nPrior	if prior = TRUE, a value specifying the number of sampling units in the implicit sample on which the prior distribution is based.
increase	an integer specifying the desired increase step for the sample size calculation.
maxSize	an integer specifying the maximum sample size that is considered in the calculation. Defaults to 5000 for efficiency. Increase this value if the sample size cannot be found due to it being too large (e.g., for a low materiality).

Details

This section elaborates on the available likelihoods and corresponding prior distributions for the likelihood argument.

- poisson: The Poisson likelihood is used as a likelihood for monetary unit sampling (MUS). Its likelihood function is defined as:

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!}$$

The conjugate *gamma(α, β)* prior has probability density function:

$$f(x; \alpha, \beta) = \frac{\beta^\alpha x^{\alpha-1} e^{-\beta x}}{\Gamma(\alpha)}$$

- binomial: The binomial likelihood is used as a likelihood for record sampling *with* replacement. Its likelihood function is defined as:

$$p(x) = \binom{n}{k} p^k (1-p)^{n-k}$$

The conjugate *beta(α, β)* prior has probability density function:

$$f(x; \alpha, \beta) = \frac{1}{B(\alpha, \beta)} x^{\alpha-1} (1-x)^{\beta-1}$$

- hypergeometric: The hypergeometric likelihood is used as a likelihood for record sampling *without* replacement. Its likelihood function is defined as:

$$p(x = k) = \frac{\binom{K}{k}\binom{N-K}{n-k}}{\binom{N}{n}}$$

The conjugate *beta-binomial(α, β)* prior (Dyer and Pierce, 1993) has probability density function:

$$f(k|n, \alpha, \beta) = \binom{n}{k} \frac{B(k+\alpha, n-k+\beta)}{B(\alpha, \beta)}$$

Value

An object of class jfaPlanning containing:

confidence	a fraction indicating the confidence level for the desired population statement.
expectedError	the specified number of errors as a fraction or as a number.
likelihood	a character indicating the specified likelihood.
N	an integer indicating the population size (only returned if it is specified).
materiality	a fraction indicating the specified materiality. Can be NULL.
minPrecision	a fraction indicating the minimum precision to be obtained. Can be NULL.
sampleSize	an integer indicating the required sample size.
errorType	a character indicating whether the expected errors where specified as a percentage or as an integer.
expectedSampleError	
	a value indicating the number of errors that are allowed in the sample.

expectedBound   a value indicating the expected upper bound if the sample goes according to plan.

expectedPrecision

         a value indicating the expected precision if the sample goes according to plan.

populationK   if `likelihood = 'hypergeometric'`, an integer indicating the assumed population errors.

prior   if a prior distribution is specified, an object of class `jfaPrior` that contains the prior distribution.

expectedPosterior

         if a prior distribution is specified, an object of class `jfaPosterior` that contains the expected posterior distribution.

report   *Generate an Audit Report*

Description

This function takes an object of class jfaEvaluation, creates a report containing the results, and saves the report to a file in your working directory.

For more details on how to use this function see the package vignette: vignette('jfa',package = 'jfa')

Usage

```
report(object = NULL, file = NULL, format = 'html_document')
```

Arguments

object	an object of class jfaEvaluation as returned by the evaluation() function.
file	a character specifying the name of the report (e.g. report.html). The report is created in your current working directory.
format	a character specifying the output format of the report. Possible options are html_document (default) and pdf_document, but compiling to .pdf format requires a local version of MikTex.

Value

A .html or .pdf file containing a report of the sample evaluation.

auditPrior selection evaluation report

Examples

```
library(jfa)
set.seed(1)

# Generate some audit data (N = 1000):
data <- data.frame(ID = sample(1000:100000, size = 1000, replace = FALSE),
                   bookValue = runif(n = 1000, min = 700, max = 1000))

# Using monetary unit sampling, draw a random sample from the population.
s1 <- selection(population = data, sampleSize = 100, units = 'mus',
                bookValues = 'bookValue', algorithm = 'random')
s1_sample <- s1$sample
s1_sample$trueValue <- s1_sample$bookValue
s1_sample$trueValue[2] <- s1_sample$trueValue[2] - 500 # One overstatement is found

e2 <- evaluation(sample = s1_sample, bookValues = 'bookValue', auditValues = 'trueValue',
                 method = 'stringer', materiality = 0.05, counts = s1_sample$count)

# Generate report
# report(e2, file = 'myFile.html')
```

---

selection	*Selecting a Sample from an Audit Population*

Description

This function takes a data frame and performs statistical sampling according to one of three algorithms: random sampling, cell sampling, and fixed interval sampling. Sampling is done on the level of two possible sampling units: records or monetary units. The returned object is of class jfaSelection and has a print() and plot() method.

For more details on how to use this function see the package vignette: vignette('jfa',package = 'jfa')

Usage

```
selection(population, sampleSize, units = 'records', algorithm = 'random',
         bookValues = NULL, intervalStartingPoint = 1, ordered = TRUE,
         ascending = TRUE, withReplacement = FALSE, seed = 1)
```

Arguments

population	a data frame containing the population of items the auditor wishes to sample from.
sampleSize	an integer specifying the number of sampling units that need to be selected from the population. Can also be an object of class jfaPlanning.
units	a character specifying the sampling units used. Possible options are records (default) for selection on the level of items or mus for selection on the level of monetary units.
algorithm	a character specifying the sampling algorithm used. Possible options are random (default) for random sampling, cell for cell sampling, or interval for fixed interval sampling.
bookValues	a character specifying the name of the column in the population that contains the book values of the items.
intervalStartingPoint	
	if algorithm = 'interval', an integer specifying the starting point of the algorithm.
ordered	a logical specifying whether to first order the items in the population according to the value of their bookValues. Defaults to TRUE.
ascending	if ordered = TRUE, a logical specifying whether to order the population bookValues from smallest to largest. Defaults to TRUE.
withReplacement	
	if algorithm = 'random', a logical specifying whether sampling should be performed with replacement. Defaults to FALSE.
seed	an integer specifying a seed to reproduce results. Defaults to 1.

Details

The first part of this section elaborates on the possible options for the units argument:

- records: In record sampling each item in the population is seen as a sampling unit. An item of $5000 is therefore equally likely to be selected as an item of $500.
- mus: In monetary unit sampling each monetary unit in the population is seen as a sampling unit. An item of $5000 is therefore ten times more likely to be selected as an item of $500.

The second part of this section elaborates on the possible options for the algorithm argument:

- random: In random sampling each sampling unit in the population is drawn with equal probability.
- cell: In cell sampling the sampling units in the population are divided into a number (equal to the sample size) of intervals. From each interval one sampling unit is selected with equal probability.
- interval: In fixed interval sampling the sampling units in the population are divided into a number (equal to the sample size) of intervals. From each interval one sampling unit is selected according to a fixed starting point (specified by intervalStartingPoint).

Value

An object of class jfaSelection containing:

population	a data frame containing the input population.
sample	a data frame containing the selection of items.
units	a character indicating the sampling units that were used to create the selection.
algorithm	a character indicating the the algorithm that was used to create the selection.
bookValues	if bookValues is specified, a character indicating the name of the book value column.
